Suppose two hosts have a long-lived TCP session over a path with a 100 msec round-trip time (RTT). Then, a link fails, causing the traffic to flow over a longer path with a 500 msec RTT. This scenario is depicted in the figure below. The original path is the straight path at the bottom. The new path is at the top.

Answer the following two questions:

WeChat: cstutorcs

Assignment Project Exam Help

Email: tutorcs@163.com

QQ: 749389476

<https://tutorcs.com>

## 1 TCP Path Change Q1

Suppose the router on the left recognises the failure immediately and starts forwarding data packets over the new path, without losing any packets. (Assume also that the router on the right recognises the failure immediately and starts directing ACKs over the new path, without losing any ACK packets.) Why might the TCP sender retransmit some of the data packets anyway?

Fill in your answer here

TCP bases its retransmission and receiving hosts. In this example, the connection has been active for some time, the DevRTT should be a very low estimate of the round-trip time between the sending and receiving hosts. As this connection has nsec before the failure. As this connection has been active for some time, the DevRTT should be pretty accurate and close to 100 msec. The RTO will thus be very similar to the RTT estimate. When the failure occurs, the interval between the failure and the arrival of the first ACK implies that the ACK packets will not arrive before the RTO expires. It is reasonable to presume the data packets have been lost, leading to retransmissions, despite the fact that no packets were actually lost.

Maximum marks: 1.5

QQ: 749389476

<https://tutorcs.com>

## 2 TCP Path Change Q2

Suppose instead that the routers do not switch to the new paths all that quickly, and the data packets (and ACK packets) in flight are all lost. What new congestion window size does the TCP sender use? Explain your answer.

Fill in your answer here

The TCP sender's adjustment depends on how the packet losses were detected. If a triple-duplicate ACK is received, the congestion window would be divided in half. However, in this case, all packets in flight are lost, so no ACKs are received, forcing the sender to detect the loss via a timeout. This timeout leads the sender to set the congestion window to 1 (i.e., 1 MSS).

Now depends on how the packet losses were detected. If a triple-duplicate ACK is received, the congestion window would be divided in half. However, in this case, all packets in flight are lost, so no ACKs are received, forcing the sender to detect the loss via a timeout. This timeout leads the sender to set the congestion window to 1 (i.e., 1 MSS).

3 TCP SYN

Why does a TCP sender use a very large retransmission timeout (e.g., several seconds) for the SYN segment?

Answer in 2 sentences at most.

Fill in your answer here

The TCP sender does not have any initial estimate of the round-trip time (RTT). Starting with a conservative retransmission timeout of several seconds prevents the excessive retransmissions that would result in a timeout that is smaller than the actual RTT.

#### 4 TCP 3 Way Handshake

Why is it necessary to have a 3 way handshake for connection establishment in TCP? Why is a 2 way handshake not sufficient?

Fill in your answer here

程序代写代做CS编程辅导

Maximum marks: 2

TCP is a bi-directional communication protocol, which means either end ought to be able to send data reliably. Both parties need to establish an Initial Sequence Number (ISN), and both parties need to acknowledge the other's ISN. Thus a two-way handshake is required in each direction as follows:

- 1) Alice picks an ISN and SYNchronises it with Bob.
- 2) Bob ACKnowledges the ISN.
- 3) Bob picks an ISN and SYNchronises it with Alice.
- 4) Alice ACKnowledges the ISN.

Steps 2 and 3 can be combined in a SYN-ACK segment, which reduces this to a 3 way handshake. A two way handshake would only allow one party to establish an ISN, and the other party to acknowledge it. Which means only one party can send data.

<https://tutorcs.com>

6 TCP Sequence Q2

How many bytes in total are sent in the four TCP segments? Only enter the numeric value in the space provided:  (3500). 程序代写代做CS编程辅导

Maximum marks: 0.75

The first segment carries 500 bytes and the second one carries 1000 bytes, the third one carries 1500 bytes and the last segment carries 500 bytes. The total data in the four segments is 3500 bytes.

WeChat: cstutorcs

Assignment Project Exam Help

Email: tutorcs@163.com

QQ: 749389476

<https://tutorcs.com>

## 7 TCP Sequence Q3

What is the last byte (number) that the TCP sender can send with certainty that the receiver's buffer will not overflow? Assume that the sender always has data to send. Explain your answer in 2 sentences.

Fill in your answer here

The window size is set to the minimum of the question window and receive window. Hence, the window size will be 13499 bytes. Since current SendBase is 7500, this implies that the last byte the sender can send with certainty is 13499.

Maximum marks: 1

WeChat: cstutorcs

Assignment Project Exam Help

QQ: 749389476

<https://tutorcs.com>

A small university campus is assigned a large address block 12.1.0.0/17, but is only using a portion of these addresses (in 12.1.1.0/24) to number its computers. The campus uses a single Internet Service Provider (ISP) to reach the rest of the Internet. The picture below shows the forwarding tables on the ISP's router (on the left) and the campus edge router (on the right).

For example, the ISP forwards destination addresses in 12.1.0.0/17 to link #2 toward the campus edge router. Both routers include a default forwarding entry (i.e., 0.0.0.0/0) that can match any destination IP address.

## 15 DV MCQ

Which of the following statements about distance vector routing are true? Multiple statements may be true.  
**Select one alternative:**

- Every router in the network knows the entire network topology.
- Poison reverse may not always solve the count-to-infinity problem. ✓
- None of the other choices are correct.
- The distance vector sent by a router is only propagated to all other routers in the network.
- A reduction in the cost of a link connected to a router will always trigger a distance vector update to be sent from this router.

WeChat: cstutorcs

---

## Assignment Project Exam Help

Maximum marks: 1

In DV, routers do not have knowledge of the entire topology, just their direct neighbours.

A reduction in the cost of a link will always trigger the execution of the DV algorithm at the node. However, a DV update will only be sent if there is a change in the DV as a result of this execution, which may not always be the case.

A DV from a node is only sent to its direct neighbours. These neighbours do not propagate the DV further. So the correct answer is that Poison Reverse may not always solve count to infinity problem. An example was shown in the lecture.

QQ: 749389476  
<https://tutorcs.com>

Consider the 8-node network shown in the figure below with link costs as shown. Note that each link shown in this network is bidirectional and has the same cost in either direction.

## 18 CRC Q1

Assume that the data bits D being transmitted over a link are 100010 and that CRC is being used to provide error detection. Suppose that a generator,  $G = 111$  is being used and known to both the sender and receiver.

- 1) What are the CRC bits (R) as computed (and included with the message) by the sender? You are not required to show your calculation, just enter the answer in the space provided. (11)

- 2) Continuing with the previous headers. Assume that 2nd, 3rd and 4th bits are swapped. The sender transmits  $\langle D, R \rangle$ . Neglect any other bits. Will the receiver be able to detect the errors? (1.5)

Select an alternative

True

False

WeChat: cstutorcs ✓

## Assignment Project Exam Help

Maximum marks: 1.5

- 1)  $R = 11$  (NOTE: you cannot add leading or trailing zeros, so 011 or 10 are not valid answers)

Email: tutorcs@163.com

$$\begin{array}{r}
 \begin{array}{c} \underline{110101} \\ 111 \sqrt{10001000} \\ \underline{111} \\ 110 \\ \underline{111} \\ 110 \\ 111 \\ 100 \\ 11 \\ 11 \end{array} & \begin{array}{c} \underline{110101} \\ 111 \sqrt{10001011} \\ \underline{111} \\ 110 \\ \underline{111} \\ 110 \\ 111 \\ 111 \\ 111 \\ 0 \end{array} \\
 \text{QQ: 749389476} & \text{0} \leftarrow \text{perfectly divided}
 \end{array}$$

The computation on the left which shows how R is computed by the sender. The computation on the right side shows you that if there are no errors while transmission, then dividing  $\langle D, R \rangle$  by G will result in a zero remainder at the receiver.

- 2) False.

$$\begin{array}{r}
 \begin{array}{c} \underline{100101} \\ 111 \sqrt{11111011} \\ \underline{111} \\ 110 \\ \underline{111} \\ 111 \\ \underline{111} \\ 111 \\ 111 \\ 0 \end{array} \\
 \text{0} \leftarrow \text{perfectly divided, CRC returns 'no error detected'}
 \end{array}$$

The computation is for the case when the ordering is left to right (i.e. 2nd, 3rd and 4th bits are counted from the left). I have not shown the computation if you count the order right to left but the answer would still be the same - False.

## 19 CRC Q2

Now assume that the data bits D are the same as the previous two questions (100010) but that a generator G = 1111 is used.

程序代写代做 CS 编程辅导

- 1) What will be the CRC bits (R) as computed (and included with the message) by the sender? You are not required to show your calculations. Simply note down R in the space provided.

(000)

- 2) Continuing with the previous headers. Assume that 2nd, 3rd and 4th bits of the frame are flipped as the frame is transmitted through the link. Will the receiver be able to

Select an alternative

- True
- False

Maximum marks: 1.5

- 1) R = 000. (NOTE: There MUST be 3 zeros in your answer, so 0 or 00 or 0000 are not valid answers)

$$\begin{array}{r}
 \text{QQ: } \underline{\text{749389476}}^{\text{110000}} \\
 1111 \sqrt{100010000} \quad 1111 \sqrt{100010000} \\
 \underline{1111} \qquad \qquad \underline{1111} \\
 \underline{1111} \qquad \qquad \underline{1111} \\
 \underline{1111} \qquad \qquad \underline{1111} \\
 \underline{00000} \qquad \qquad \qquad \qquad \qquad \text{00000} \leftarrow \text{perfectly divided}
 \end{array}$$

The computation on the left shows how R is computed by the sender. The computation on the right shows the corresponding computation at the receiver assuming there are no errors in transmitting  $\langle D, R \rangle$

$$\begin{array}{r}
 \text{2) } \underline{\text{100011}} \\
 1111 \sqrt{111110000} \\
 \underline{1111} \\
 \underline{01000} \\
 \underline{1111} \\
 \underline{1110} \\
 \underline{1111} \\
 \text{001} \leftarrow \text{not perfectly divided, CRC returns 'error detected'}
 \end{array}$$

The computation shown is for the case when the ordering is left to right (i.e. 2nd, 3rd and 4th bits are counted from the left). I have not shown the computation if you count the order right to left but the answer would still be the same - True.

Consider the network shown in the figure below. You may assume that all switch tables are empty at the start.

Answer the following three questions. Note that links you can use notations such as A-S1 (the link connecting A to S1) and S1-S4 (the link connecting S1 to S4).

Assignment Project Exam Help

Email: tutorcs@163.com

QQ: 749389476

<https://tutorcs.com>

**21 Switch Q2**

Assume that host F now sends a frame to Host A. Indicate all links in the network that this frame is transmitted on and explain why.

Fill in your answer here

The frame would be transmitted on F-S2. When the frame reaches S2, it would now have learnt that host A is reachable along the link S2-S4. So S2 would selectively forward the frame on this link (i.e., S2-S4).  
When the frame reaches S4, S4 would now have learnt that host A is reachable along the link S4-S1. So S4 would selectively forward the frame on this link (i.e., S4-S1).  
When the frame reaches S1, S1 would now have learnt that host A is reachable along the link S1-A. So S1 would selectively forward the frame on this link (i.e., S1-A).

## 26 Keys

Suppose  $N$  people want to communicate with each of  $N - 1$  other people using symmetric key encryption. All communication between any two people,  $i$  and  $j$ , is visible to all other people in this group of  $N$ , and no other person in this group should be able to decode their communication. How many keys are required in the system as a whole?

Now suppose that public key encryption is used. How many keys are required in this case?

Provide a short explanation for your answer below.

**Fill in your answer here**

Symmetric Key Encryption:

A symmetric key would be required by each person for each of the  $N - 1$  other people. So Person 1 would require  $(N - 1)$  keys to communicate with others. Person 2 would require  $(N - 2)$  keys, Person 3 would require  $(N - 3)$  and so on. Thus total keys required =  $(N - 1) + (N - 2) + (N - 3) \dots + 1 = N(N - 1)/2$ .

Public Key Encryption:

Each person would only require a public-private key pair. So the total keys required =  $N$  pairs of public, private key pairs.

Maximum marks: 1

The role of the CA is to certify the public keys of users who register with it. The CA does so by adding a digital signature (signed by the CA's private key) to the public key of the user. Others can verify the certificate by applying the CA's public key.

**28 Email**

SuperMail wants every email to be authenticated and protected from modification or tampering while it is in transit from the sender to the receiver. Suppose Alice is sending an email  $M$  to Bob. Assume that a SuperMail employee proposes the following solution: Alice's software should encrypt  $M$  using Bob's public key. In other words, Alice's software should send  $E_{KB+}(M)$  to Bob. Can you comment on whether the employee's solution meets the requirement stated above. Justify your answer.

Fill in your answer here

Encryption does not provide authentication. Anybody else than Alice can send the exact same message to Bob. Bob won't be able to tell who the sender was..

## 29 Putting it together

You walk into a room, connect your laptop to an Ethernet outlet, and type in your web browser a URL of a web page. List all the messages/packets that you expect your laptop to send or receive until you download the web page. Assume that your laptop is configured with the IP address of a local DNS server, as well as the IP address of a default gateway (a router through which traffic from your laptop will exit the local IP subnet).

Fill in your answer here

Format | B I U x | D E F G H I J K L M N O P Q R S T | Σ Σ | X

Since your computer's ARP cache does not contain the MAC addresses of the first-hop router, your computer will use ARP protocol to get the MAC address of the first-hop router.

Your computer will first query the local DNS server to find the IP address of the Web page you would like to download.

Once your computer has the IP address of the Web page, then it will establish a TCP connection and send out a HTTP request via the first hop router (assuming the Web server does not reside inside the local network). The HTTP request message will be encapsulated in a TCP segment, and then further encapsulated in an IP datagram and then an Ethernet frame.

Your computer sends the Ethernet frame destined to the first-hop router. Once the router receives the frame, it passes the encapsulated IP datagram up to the IP layer, checks its routing table, and then sends the IP datagram encapsulated in an Ethernet frame to the next-hop (the interface corresponding to the next-hop in the routing table). Then the IP datagram will be routed through the Internet until they reach the Web server.

The server hosting the Web page will send back the Web page to your computer via HTTP response messages. Those messages will be encapsulated in TCP segments and then further into IP datagrams and link layer frames. Those IP datagrams follow the routes (as per the routing algorithms used) and finally reach your first-hop router, and then the router will forward them to your computer by encapsulating them into Ethernet frames.
